Laservision, Inc., Trabers, Alaska, Greece

Background
We have presented our experience over the last 6 years in using this study as a standard form to treat AAO patients. With goal to shorten the duration and potentially increase efficacy we opted to study a model of CXL of higher UVA light intensity (from 7mW/cm² to 7 mW/cm²) and the same volume (1.75 repeat riboflavin sodium phosphate solution).

Objective: To evaluate the safety and efficacy of higher UVA fluence and shorter duration for collagen cross-linking in KCN.

Design: Prospective, randomized controlled case series.

Methods: 13 patients with bilateral keratoconus were studied. All cases were evaluated for UCVA, BCVA, refraction, keratometry change (KC), topography change, endothelial cell changes and corneal clarity. All eyes received CXL with repeat 0.1% riboflavin solution drop and in regard to UVA they were randomized for each patient: 11 eyes were CXL with 7mW/cm² for 15 minutes and their contralateral eyes with 3mW/cm² for 30 minutes. Mean follow up was 1.3 years.

Results:
The mean improvement of UCVA was 0.2 to 0.4, BCVA improved from 0.4 to 0.7. The average change of spherical equivalent was 1.5D reduction in myopia, the average change in cylinder was 2.1D reduction. The average highest keratometry was 51.2D post op and changed to 48.5D post op. There was no statistical difference in the means in the 2 groups.

Conclusions:
Shorter duration, higher UVA fluence CXL appears to be as safe and as effective as randomization of extent in KCN. It may cause less cell toxicity due to lesser corneal dehydration (see time) and shorter exposure of keratocytes and endothelial cells to UV light along with riboflavin. Further studies are needed to validate this data.

	UCVA	BCVA	avg KC change	cylinder change	KC change	endo change	clarity change
7mW	0.2	0.3	1.5D	2.2D	100	2.3	0
3mW	0.2	0.3	1.4D	2D	200	2.1	0

Costas Karabatsas¹

¹LaserVision.gr Clinical and Research Eye Institute, Athens, Greece; ²New York University Medical School, New York, NY, USA

Purpose: To compare 1-year results: safety, efficacy, refractive and keratometric stability, of femtosecond myopic laser-assisted in situ keratomileusis (LASIK) with and without concurrent prophylactic high-fluence cross-linking (CXL) (LASIK-CXL).

Methods: We studied a total of 155 consecutive eyes planned for LASIK myopic correction. Group A represented 73 eyes that were treated additionally with concurrent prophylactic high-fluence CXL; group B included 82 eyes subjected to the stand-alone LASIK procedure. The following parameters were evaluated preoperatively and up to 1-year postoperatively: manifest refractive spherical equivalent (MRSE), refractive astigmatism, visual acuity, corneal keratometric readings (K-readings).

Figure 8 Stability of corneal keratometry for (A) the LASIK-CXL group and (B) the stand-alone LASIK group, expressed in diopters (D), up to 1-year postoperatively. Abbreviations: CXL, cross-linking; LASIK, laser-assisted in situ keratomileusis.

**Collagen Cross-Linking (CXL) With Sequential Topography-Guided PRK
A Temporizing Alternative for Keratoconus to Penetrating Keratoplasty**

A. John Kanellopoulos, MD^{1,2} and Perry S. Binder, MS, MD³

Purpose: To assess the effectiveness of ultraviolet A (UVA) radiation-induced collagen cross-linking (CXL) on keratoconus (KC) progression.

Methods: A patient with bilateral, progressive KC underwent UVA radiation (3 mW/cm²) for 30 minutes after topical 0.1% riboflavin drops over dehydrated corneas. Twelve months later, a topography-guided penetrating keratoplasty (PRK, wavefront 400 Hz Excimer) treatment was performed in 1 eye for a refractive error of -5.50 +4.00 × 155 by using an attempted treatment of -2.25 +3.00 × 155. All corneal topography follow-up visits to 18 months, uncorrected visual acuity (UCVA), best spectacle-corrected visual acuity (BSCVA), pachymetry, and topography were performed.

Results: In the treated left eye, the UCVA after the UVA CXL improved from 20/100 to 20/60, and the BSCVA improved from 20/20 to 20/40. Eighteen months after the topography-guided PRK, the UCVA was 20/20, and the BSCVA was 20/15, with a refractive error of Plus -0.75 × 120. The cornea was stable, and the endothelial cell count remained unchanged. The untreated right eye continued to progress during the same period.

Conclusion: The significant clinical improvement and the superior stability of cornea that a year after UVA CXL and subsequent PRK compared with the untreated right eye seems to validate this treatment approach for KC. An adjusted management may be considered in the absence of cross-linked cornea tissue to avoid keratoplasty.

CASE REPORT

A 29-year-old male patient had been treated with gas-permeable contact lenses 10 years before the presentation. Because of debilitating glare papilloe's, contact lenses no longer able to wear because of poor vision and astigmatism. At the time of his presentation, his uncorrected visual acuity (UCVA) was 20/100 in the right eye and 20/100 in the left eye, and his best spectacle-corrected visual acuity (BSCVA) was 20/30 OD (monocular refraction: -3.75 +0.75 × 091 and 20/30 OS (monocular refraction: -3.75 +0.75 × 042). His keratometry readings were as follows: OD, 41.23 × 41.23 × 180, OS, 45.02 × 45.02 × 90 (Lipson's Keratograph, Broughton, Kentucky).

Slit-lamp examination of the right eye failed to show clinical findings associated with keratoconus such as a Fleischer ring, Vogt striae, or a markedly progressive form of the crescent or paracentral scars. The central pachymetry was 329 µm (Orbicon II, Bausch and

Management of Corneal Ectasia After LASIK/Kanellopoulos & Binder

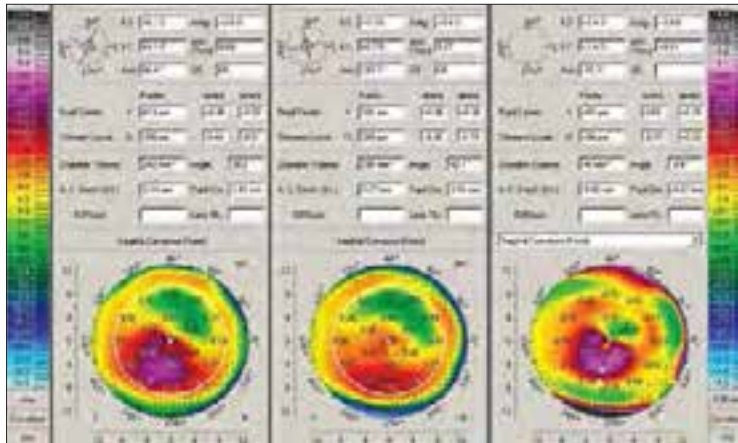

Figure 4. Case 4. Pentacam comparison of the right eye. The left column shows the data and topography before topography-guided PRK/CXL. The center column shows the postoperative data and topography. The right column shows the difference (pre- minus postoperative).

Management of Corneal Ectasia After LASIK/Kanellopoulos & Binder

Figure 2. Case 2. Topography on the left shows marked inferior steepening before topography-guided PRK/CXL treatment. The topography on the right shows the same cornea 18 months after topography-guided PRK/CXL with marked flattening of the corneal ectasia and normalization of the cornea.

Figure 3. Case 3. Clinical course of the right eye. **A)** Topography 3 years after LASIK demonstrates irregular astigmatism and marked inferior corneal steepening. Uncorrected distance visual acuity was 20/40 and corrected distance visual acuity was 20/20 with refraction of +1.50 -2.00 x 65. **B)** Topography 3 months after topography-guided PRK/CXL procedure demonstrates a flatter and normalized cornea. Uncorrected distance visual acuity was 20/15. **C)** Topographic reproduction of the topography-guided PRK treatment plan with the WaveLight platform. This platform plans to remove tissue in an irregular fashion to normalize the corneal ectasia seen in Figure 3A. **D)** Comparison map, derived from subtracting image B from A, represents the topographic difference in this case 3 months after the combined treatment. The paracentral flattening is self-explanatory, as the PRK and CXL have flattened the cone apex. The superior nasal arcuate flattening represents the actual part-hyperopic correction, which the topography-guided treatment has achieved, to accomplish steepening in the area central to this arc. Thus, the topography-guided treatment has normalized the ectatic cornea by flattening the cone apex and at the same time by "steepening" the remainder of the central cornea.

ectasia and was offered Intacs (Addition Technology Inc, Des Plaines, Illinois) or a corneal transplant. He presented to our institution in September 2007, 3 years after LASIK. Uncorrected distance visual acuity was 20/40 in the right eye and 20/15 in the left eye. Manifest refraction was +1.50 -2.00 x 65 (20/20) in

the right eye and plano (20/15) in the left eye. Keratometry was 41.62@65/43.62@155 in the right eye and 41.75/42.12@10 in the left eye. Central ultrasound pachymetry was 476 μm in the right eye and 490 μm in the left eye.

On September 13, 2007, 39 months after LASIK,

Novel Placido-derived Topography-guided Excimer Corneal Normalization With Cyclorotation Adjustment: Enhanced Athens Protocol for Keratoconus

Anastasios John Kanellopoulos, MD; George Asimellis, PhD

ABSTRACT

PURPOSE: To comparatively investigate the efficacy of the enhanced Athens Protocol procedure guided by novel Placido-derived topography with cyclorotation compensation (the cyclorotation adjusted group) to similar cases guided by Scheimpflug-derived topography without cyclorotation compensation (the non-cyclorotation adjusted group).

METHODS: Two groups were evaluated: the cyclorotation adjusted group (n = 110 eyes) and the non-cyclorotation adjusted group (n = 110 eyes). Analysis was based on digital processing of Scheimpflug imaging derived curvature difference maps preoperatively and 3 months postoperatively. The vector (r, θ) corresponding to the steepest corneal point (cone) on the preoperative surgical planning map (r₀, θ_0) and on the curvature difference map (r₁, θ_1) were computed. The differences between the peak topographic angular data ($\Delta\theta = |\theta_1 - \theta_0|$) and weighted angular difference ($W\Delta\theta = \Delta\theta \times \Delta r$) were calculated.

RESULTS: For the cyclorotation adjusted group, $\Delta\theta$ was $7.18^\circ \pm 7.53^\circ$ (range: 0° to 34°) and $W\Delta\theta$ was 3.43 ± 4.76 mm (range: 0.00 to 21.41 mm). For the non-cyclorotation adjusted group, $\Delta\theta$ was $14.50^\circ \pm 12.65^\circ$ (range: 0° to 49°) and $W\Delta\theta$ was 10.23 ± 15.15 mm (range: 0.00 to 80.56 mm). The cyclorotation adjusted group appeared superior to the non-cyclorotation adjusted group, in both the smaller average angular difference between attempted to achieved irregular curvature normalization and in weighted angular difference, by a statistically significant margin ($\Delta\theta$: $P = .0058$; $W\Delta\theta$: $P = .015$).

CONCLUSIONS: This study suggests that employment of the novel Placido-derived topographic data of highly irregular corneas, such as in keratoconus, treated with topography-guided profile with cyclorotation compensation leads to markedly improved cornea normalization.

J Refract Surg. 2015;31(11):768-773.]

Corneal cross-linking (CXL) is considered a valid option for progressive keratoconus/corneal ectasia treatment.¹ By increasing corneal biomechanical strength, CXL results in keratectasia arrest.² In addition, CXL has also been shown to improve corneal irregularity and reduce central anterior corneal steepening.³ Combined with CXL, partial anterior surface normalization via topography-guided customized partial excimer laser ablation may offer, in addition to keratectasia arrest, improved topographic and refractive outcomes.^{3,4} The Athens Protocol comprises phototherapeutic keratectomy (PTK) of 50 μ m, a partial photorefractive keratectomy (PRK) for the topography-guided customized anterior surface normalization, and high-fluence CXL for corneal stabilization.⁵ Long-term results⁶ and anterior segment optical coherence tomography quantitative findings⁷ have demonstrated the stability of the procedure in large cohorts of patients. Variations of this technique have been applied and reported globally.⁸⁻¹⁴

Because the topography-guided ablation step of the procedure bears a high degree of customization, the impact of effective alignment between treatment planning based on the topography-derived data and surgically applied ablation pattern is pivotal for a successful outcome. Critical parameters affecting alignment are horizontal and vertical eye movements, eye pupil centroid shift, and possible cyclorotation. The significance of these principles has been reported preoperatively and intraoperatively in refractive procedures.¹⁵ High-speed active eye tracking along with cyclorotational topographic adjustment (CTA) has been introduced during the past 2 years in refractive lasers such as the EX500 excimer laser (Alcon Laboratories, Inc., Fort Worth, TX), which

Corneal Refractive Power and Symmetry Changes Following Normalization of Ectasias Treated With Partial Topography-Guided PTK Combined With Higher-Fluence CXL (The Athens Protocol)

Anastasios John Kanellopoulos, MD; George Asimellis, PhD

ABSTRACT

PURPOSE: To investigate improvements in refraction, corneal astigmatism, and symmetry following partial topography-guided photorefractive keratectomy (PTK) combined with higher-fluence cross-linking (CXL) in keratoconus, and to assess the impact of these changes on visual acuity and contrast sensitivity. The authors hypothesized that combined PTK and CXL would result in improved visual acuity and contrast sensitivity over following treatment with PTK alone.

METHODS: Nineteen eyes of 10 patients (9 males and 10 females) with keratoconus were treated with partial topography-guided PTK followed by high-fluence CXL. Preoperative and postoperative data were collected at 1, 3, 6, and 12 months.

RESULTS: Refractive improvement, average anterior curvature flattening, and increase in keratometric values were observed. Mean preoperative spherical equivalent refraction was -11.05 ± 6.52 diopters (D) (range: -1.0 to -21.1 D) and -0.79 ± 0.38 D (range: -1.2 to -0.4 D) for spherical and cylindrical components, respectively. Postoperative spherical equivalent refraction was -6.29 ± 3.25 D (range: -1.0 to -11.5 D) and -0.16 ± 0.21 D (range: -0.33 to 0.01 D) for spherical and cylindrical components, respectively. The difference in spherical equivalent refraction was 4.76 ± 2.73 D (range: 1.87 to 8.23 D), whereas the difference in cylindrical refraction was 0.63 ± 0.17 D (range: 0.47 to 0.80 D). The difference in anterior curvature was 1.67 ± 0.42 D (range: 0.83 to 2.51 D). The difference in keratometric values was 4.80 ± 1.82 D (range: 2.98 to 6.62 D). The difference in visual acuity was 0.18 ± 0.02 logMAR (range: 0.15 to 0.21 logMAR) and the difference in contrast sensitivity was 1.87 ± 0.21 cycles/degree (range: 1.63 to 2.11 cycles/degree). The difference in contrast sensitivity was 1.87 ± 0.21 cycles/degree (range: 1.63 to 2.11 cycles/degree). The difference in contrast sensitivity was 1.87 ± 0.21 cycles/degree (range: 1.63 to 2.11 cycles/degree).

CONCLUSIONS: Partial topography-guided PTK combined with higher-fluence CXL resulted in improved refractive, keratometric, and symmetry changes. The authors hypothesized that combined PTK and CXL would result in improved visual acuity and contrast sensitivity over following treatment with PTK alone.

KEY WORDS: keratoconus; photorefractive keratectomy; cross-linking; visual acuity; contrast sensitivity

INTRODUCTION: Keratoconus is a degenerative bilateral, noninflammatory disorder characterized by ectasia, thinning, and irregular corneal topography.¹ The disorder usually has onset at puberty and often progresses until the third decade of life, may manifest asymmetrically in the two eyes of the same patient, and can present with unpredictable visual acuity, particularly in relation to corneal irregularities.² One of the acceptable options³ for progressive keratoconus management is corneal collagen cross-linking (CXL) with riboflavin and ultraviolet-A.⁴

Keratoconus assessment employs indicators such as keratometric values, inferior-superior index, skew percentage, astigmatism, and the KISA% index.⁵ Acceptable quantitative keratometric criteria include central corneal refractive power larger than 47.2 diopters (D), inferior-superior dioptric asymmetry larger than 1.2 D, and simulated astigmatism, expressed as the difference between steep and flat keratometric values greater than 1.5 D.⁶ The steep and flat meridian keratometric values correspond to the smaller and larger anterior corneal curvature radius, respectively.

Corneal cross-linking (CXL) is an in vivo intrastromal photo-oxidative technique with riboflavin and ultraviolet-A light aiming to address the advancing corneal ectasia and, consequently, the keratoconus progression. With CXL, additional covalent bonding between stromal collagen can be achieved, which stabilizes the collagen framework structure.⁷ The remodeling effects of CXL on the cornea can be described by the reduction of mean anterior surface keratometric values.⁸ Few studies have been published on the quantitative link between anterior and posterior keratometric values in keratoconic eyes or particularly on the postoperative effects of CXL on either corneal surface.

This study aims to investigate the distribution of and relationship between anterior and posterior corneal keratometric values and simulated anterior and posterior astigmatism on a large group of clinically diagnosed, untreated keratoconic eyes, and the 1-year postoperative effects on both anterior and posterior keratometric values and astigmatism induced by a combined procedure known as the Athens Protocol,^{9,6} which intends to arrest the keratoconus progression and normalize the anterior corneal surface.

Keratoconus Management: Long-Term Stability of Topography-Guided Normalization Combined With High-Fluence CXL Stabilization (The Athens Protocol)

Anastasios John Kanellopoulos, MD; George Asimellis, PhD

ABSTRACT

PURPOSE: To investigate refractive, topographic, pachymetric, and visual rehabilitation changes induced by partial topography-guided excimer laser ablation in combination with accelerated, high-fluence cross-linking.

METHODS: Two hundred thirty-four keratoconus patients subjected to the Athens Protocol procedure were studied for visual acuity, keratometry, astigmatism, and anterior surface topography changes up to 3 years postoperatively. Topographic imaging (Orbscan II; Bausch & Lomb) was used.

RESULTS: Mean visual acuity changes at 3 years postoperatively were $+0.38 \pm 0.31$ (range: -0.34 to $+1.01$) for uncorrected distance visual acuity and $+0.20 \pm 0.21$ (range: -0.33 to $+0.90$) for corrected distance visual acuity. Mean H1 (the mean) keratometric values were 46.56 ± 3.83 diopters (D) (range: 39.75 to 58.30 D) preoperatively, 44.44 ± 3.97 D (range: 36.10 to 59.30 D) 3 months postoperatively, and 43.22 ± 3.80 D (range: 36.00 to 53.70 D) up to 3 years postoperatively. The average index of surface variance was 98.46 ± 43.47 (range: 17 to 209) preoperatively and 76.50 ± 38.41 (range: 7 to 190) up to 3 years postoperatively. The average index of height decentration was 0.021 ± 0.023 mm (range: 0.006 to 0.275 mm) preoperatively and 0.017 ± 0.040 mm (range: 0.001 to 0.208 mm) up to 3 years postoperatively. Mean minimum central thickness was 481.01 ± 40.02 μ m (range: 297 to 647 μ m) preoperatively, 533.95 ± 53.90 μ m (range: 180 to 880 μ m) 3 months postoperatively, and 570.52 ± 58.21 μ m (range: 218 to 800 μ m) up to 3 years postoperatively.

CONCLUSIONS: The Athens Protocol to arrest keratoconus progression and improve corneal regularity with topographic stability and effective results as a keratoconus management option. Progressive refractive and topographic changes were observed during correlation of the surface normalized to avoid overcorrection.

KEY WORDS: keratoconus; topography-guided; cross-linking; visual acuity; contrast sensitivity

INTRODUCTION: Keratoconus is a degenerative bilateral, noninflammatory disorder characterized by ectasia, thinning, and irregular corneal topography.¹ The disorder usually has onset at puberty and often progresses until the third decade of life, may manifest asymmetrically in the two eyes of the same patient, and can present with unpredictable visual acuity, particularly in relation to corneal irregularities.² One of the acceptable options³ for progressive keratoconus management is corneal collagen cross-linking (CXL) with riboflavin and ultraviolet-A.⁴

Keratoconus is a degenerative bilateral, noninflammatory disorder characterized by ectasia, thinning, and irregular corneal topography.¹ The disorder usually has onset at puberty and often progresses until the third decade of life, may manifest asymmetrically in the two eyes of the same patient, and can present with unpredictable visual acuity, particularly in relation to corneal irregularities.² One of the acceptable options³ for progressive keratoconus management is corneal collagen cross-linking (CXL) with riboflavin and ultraviolet-A.⁴

To further improve the topographic and refractive outcomes, CXL can be combined with customized anterior surface normalization.⁵⁻⁷ Our team has developed a procedure^{8,9} we have termed the Athens Protocol,¹⁰ involving sequentially excimer laser epithelial debridement (50 μ m), partial topography-guided excimer laser stromal ablation, and high-fluence ultraviolet-A irradiation (10 mW/cm²), accelerated (10', or minutes) CXL. Early results¹¹ and anterior segment optical coherence tomography quantitative findings¹² are indicative of the long-term stability of the procedure.

Detailed studies on postoperative visual rehabilitation and anterior surface topographic changes by such combined CXL procedures are rare,¹³⁻¹⁶ particularly those reporting results longer than 1 year. This study aims to investigate safety and efficacy of the Athens Protocol procedure by analysis of long-term (3-year) refractive, topographic, pachymetric, and visual rehabilitation changes on clinical keratoconus management with the Athens Protocol in a large number of cases.

PATIENTS AND METHODS

This clinical study received approval by the Ethics Committee of our Institution and adhered to the tenets of the Declaration

From Laservision.gr Eye Institute, Athens, Greece (AJK, GA); and New York University School of Medicine, New York, New York (AJK).

Conclusions

- The Athens Protocol (partial topo-guided PTK combined with CXL) appears to be safe and effective in ectasia stabilization, and visual rehab over 12 years later.
- Alternative treatments are CXL alone
- Contact lenses: RGPs and/or Scleral lenses
 - ICRS
 - Lamellar keratoplasty
 - Penetrating keratoplasty

Corneal Refractive Power and Symmetry Changes Following Normalization of Ectasias Treated With Partial Topography-Guided PTK Combined With Higher-Fluence CXL (The Athens Protocol)

SD = standard deviation; D = diopter; Max = maximum; Min = minimum

Figure 1. Scatter and fitted line plots of posterior astigmatism expressed in diopters (D) versus anterior astigmatism (also expressed in D) with 95% confidence intervals (CI) and 95% prediction intervals (PI). (Top) Before and (bottom) after treatment.

treatment, r^2 was 0.407 and P value less than .001 (Table 2).

Data analysis indicates that the mean of the paired differences regarding the flat anterior keratometric val-

ues was reduced (flattened) postoperatively by -3.09 ± 2.69 D, or -6.56% , and was statistically significant ($P < .05$) (Table 2). The uncertainty associated with estimating the difference from sample data indicated, with a 95% confidence interval, that the true difference was between -2.76 and -3.41 D. The steep anterior keratometric values showed a postoperative flattening by -4.19 ± 2.96 D, or -8.19% , again statistically significant ($P < .05$). The true 95% difference was between -3.84 and -4.55 D.

The mean of the paired differences regarding the flat posterior keratometric values showed an increase of $+0.12 \pm 0.61$ D, or $+1.76\%$ (considering the negative sign of the posterior keratometric values). The 95% true difference was between -0.191 and -0.0440 D. The analysis for the steep posterior keratometric values showed a postoperative change of -0.02 ± 0.55 D or $+0.04\%$ (95% true difference between -0.0485 and $+0.0829$ D). These differences were not statistically significant (flat $P = .135$, steep $P = .606$).

DISCUSSION

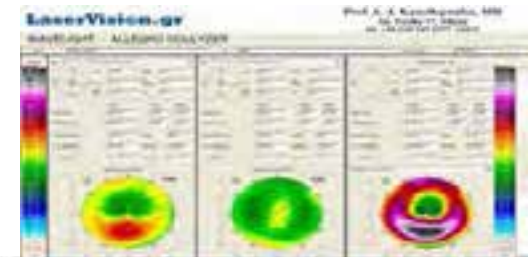

In this study, a rotating Scheimpflug camera was employed to measure both the anterior and posterior corneal curvature in a large number (267) of keratometric cases, before and after (1 year postoperatively) a combined CXL and anterior surface excimer laser normalization. In the case of keratoconus, highly irregular keratometric values were present. For example, the simultaneous investigation of anterior and posterior corneal keratometric values has indicated statistically significant differences between normal and keratoconus-suspect eyes.¹⁶ In a study evaluating keratometric values in keratoconic compared to normal eyes, the

ORIGINAL RESEARCH

**Topography-modified refraction (TMR):
adjustment of treated cylinder amount and axis to
the topography versus standard clinical refraction
in myopic topography-guided LASIK**

Anastasios John
Kanellopoulos^{1,2}

¹LaserVision Clinical and Research
Institute, Athens, Greece;
²Department of Ophthalmology, NYU
Medical School, New York, NY, USA

Purpose: To evaluate the safety, efficacy, and contralateral eye comparison of topography-guided myopic LASIK with two different refraction treatment strategies.

Setting: Private clinical ophthalmology practice.

Patients and methods: A total of 100 eyes (50 patients) in consecutive cases of myopic topography-guided LASIK procedures with the same refractive platform (FS200 femtosecond and EX500 excimer lasers) were randomized for treatment as follows: one eye with the standard clinical refraction (group A) and the contralateral eye with the topographic astigmatic power and axis (topography-modified treatment refraction; group B). All cases were evaluated pre- and post-operatively for the following parameters: refractive error, best corrected distance visual acuity (CDVA), uncorrected distance visual acuity (UDVA), topography (Placido-disk based) and tomography (Scheimpflug-image based), wavefront analysis, pupillometry, and contrast sensitivity. Follow-up visits were conducted for at least 12 months.

Results: Mean refractive error was -5.5 D of myopia and -1.75 D of astigmatism. In group A versus group B, respectively, the average UDVA improved from 20/200 to 20/20 versus 20/16; postoperative CDVA was 20/20 and 20/13.5; 1 line of vision gained was 27.8% and 55.6%; and 2 lines of vision gained was 5.6% and 11.1%. In group A, 27.8% of eyes had over -0.50 diopters of residual refractive astigmatism, in comparison to 11.7% in group B ($P < 0.01$). The residual percentages in both groups were measured with refractive astigmatism of more than -0.5 diopters.

Conclusion: Topography-modified refraction (TMR): topographic adjustment of the amount and axis of astigmatism treated, when different from the clinical refraction, may offer superior outcomes in topography-guided myopic LASIK. These findings may change the current clinical paradigm of the optimal subjective refraction utilized in laser vision correction.

Keywords: TMR, topography-modified refraction, myopic LASIK, femtosecond laser, FS200, EX500 excimer laser, long-term stability, regression, astigmatism correction, post-LASIK refraction

Introduction

Laser vision correction has been established over the last 2 decades as a safe and effective intervention, with Laser-assisted in situ keratomileusis (LASIK) being one of the main techniques practiced globally.^{1,2}

Femtosecond laser-assisted LASIK has become a popularized modification over the last decade and over the standard LASIK technique utilizing mechanical microkeratomes.^{3,4}

Comparison of topography cylinder adjustment in LASIK vs standard refraction

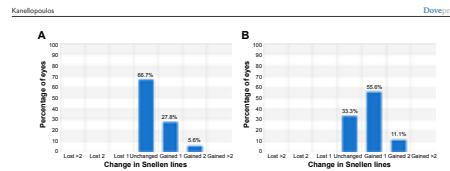

Figure 4 Safety distance visual acuity graph (percentage of eyes with gain/loss in Snellen lines) at 3-month visit (A) group A and (B) group B.
Notes: Group A: one eye with the standard clinical refraction; Group B: the contralateral eye with the topographic astigmatic power and axis (topography-modified treatment refraction).

Figure 5 Defocus equivalent results at 3-month visit (A) group A and (B) group B.
Notes: Group A: one eye with the standard clinical refraction; Group B: the contralateral eye with the topographic astigmatic power and axis (topography-modified treatment refraction).

Figure 6 Probability of spherical equivalent (SE) correction, showing achieved SE versus attempted SE (A) group A and (B) group B.
Notes: Group A: one eye with the standard clinical refraction; Group B: the contralateral eye with the topographic astigmatic power and axis (topography-modified treatment refraction). Green marks show outcomes within 0.25 diopters of attempted vs achieved; blue marks show attempted vs achieved of under 0.25 diopters (under-corrections); red marks show attempted vs achieved of over 0.25 diopters (over-corrections).

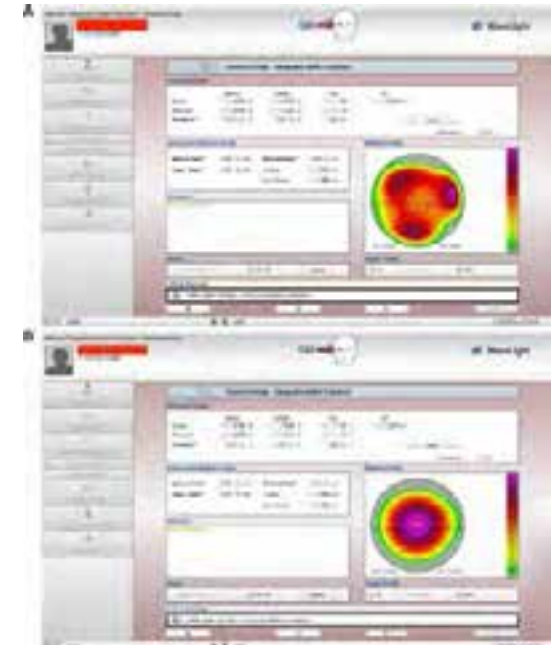

Figure 1 Image A shows the topography-guided treatment when refractive error is adjusted by the user to zero sphere and zero cylinder. This image allows the user to visualize the corrections made by the software and added to the surgeon correction in order to normalize the anterior cornea curvature to the cornea vertex. Image B illustrates the topography treatment pattern after the refraction has been adjusted by the user to the desired sphere and cylinder and includes the changes noted in image A.
Notes: "Clinical" is the clinical refraction dialled by the user into the system; the "measured" refraction is the cylindrical amount and axis calculated by the topography software, to be corrected to the anterior cornea can be maximally normalized in regard to the cornea vertex; "modified" represents the surgeon/user adjusted data.
Abbreviations: 3D, three-dimensional; max, maximum; cen, center; trans, transition zone; res, residual; VD, vertex distance.

the right of the top image in Figure 1. The trefoil-like image is also presented here in correlation with the pupillary aperture, also captured by the Vario topographer, and in this top window it shows clearly decentration to the trefoil-like

normalization ablation, revealing angle-kappa compensation by the topography software. This ablation pattern will induce some myopia and it was calculated that in order to keep it neutral there is a need to add -0.25 D of myopia to the clinical

2016 Course's Mutual Outline (Copenhagen and Chicago)

8:00
 Breakfast - Registration

8:30-11:30

- Introduction to current cornea diagnostics and their relative differences: Placido Topography, Scheimpflug tomography, Anterior segment OCT, LED color reflection topography.
- Corneal epithelial mapping and its clinical relevance in diagnosis and treatment
- Basic principles in employing topography data (Scheimpflug based and/or Placido-based) in the customization of an excimer corneal ablation. Technology overview and case presentations, with the Wavelight, Schwind and Ivis platforms.
- Topography astigmatism, centroid and angle kappa considerations for possible revision of the clinical refraction used in each ablation

11:30-12:30

Discussion lunch

12:30-15:30

- Topography customized methodology for virgin myopic and hyperopic eyes
- Topography customized methodology for irregular corneas (previously treated: RK, decentered and/or irregular ablations, as well as irregular and ectasia cases)
- Anticipating asphericity and sphere compensatory nomograms for better spherical correction and emmetropia.
- Participants will gain access to an online database with over 100 cases examples (pre-op data, treatment design, treatment video, postop data and overview of what went well and what potentially went off-target)
- Complications assessment and management.

• Each participant will have the chance to design several treatments on site!

The course will be limited to 30 participants.

Advanced registration and information:

<http://www.topo-guided.com/>

Topography - Guided University Courses 2016:

- Correlation of multiple corneal imaging devices may enhance accuracy of assessment by including possible epithelial remodeling data, and limiting specific limitations of Placido-based, Scheimpflug-based and color LED refraction Topography.
- When using topography maps in laser corneal ablation, all these parameters are considered under a much more meticulous and critical perspective. Although originally designed to treat irregular eyes, it has recently become apparent, that topo-guided treatments may be superior for routine myopic and/or hyperopic laser vision correction.
- This vigorous didactic course and wet lab on topography-customized corneal ablations will focus on familiarizing the small number of participants on multiple imaging assessment and interpretation, data acquisition and treatment modifications with hands-on the design platforms and data present on-site.
- Additionally, the participants will be offered access to a very large databank with most topo-guided scenario treatments and outcomes.

Customized CXL for KCN!

Epithelial remodeling after partial topography-guided normalization and high-fluence short-duration crosslinking (Athens protocol): Results up to 1 year

Anastasios John Kanellopoulos, MD, George Asimellis, PhD

ARTICLE

EPITHELIAL REMODELI

Figure 2. Comparative AS-OCT epithelial thickness (μm) 3-D maps shows an image from Group A taken 1 year postoperatively and an image from Group B (I = inferior; IN = inferior-nasal; IT = inferior-temporal; N = nasal; S = superior; SN = superior-nasal; ST = superior-temporal; T = temporal).

A. John Kanellopoulos, MD

Figure 3. Mean and center epithelial thicknesses in the 3 groups. Error bars correspond to the SD (KCN = keratoconus, no treatment).

Figure 4. Epithelial thickness variability and range in the 3 groups. Error bars correspond to the SD (KCN = keratoconus, no treatment).

The findings in the current study agree with those in our previous study¹; that is, although an overall thicker epithelium with large variations can be observed clinically and topographically in eyes with keratoconus, in eyes treated with CXL the variability in epithelium thickness and topographic thickness decreased by a statistically significant margin and was more uniform. We have theorized that epithelial hyperplasia in biomechanically unstable corneas (ie, increased epithelial regrowth activity) might be associated with a more elastic cornea.¹ The laboratory and clinical findings of increased corneal rigidity after CXL are widely accepted,^{23–25} including in studies of accelerated high-fluence CXL.²⁶

In conclusion, we present the results in a comprehensive study of the postoperative development of corneal epithelial thickness distribution after keratoconus management using combined anterior corneal normalization by topography-guided excimer ablation and accelerated CXL. The epithelial healing processes can be monitored by AS-OCT with ease in a clinical setting, expanding the clinical application of this technology. Our findings suggest less topographic variability and overall reduced epithelial thickness distribution in keratoconus eyes treated with CXL using the Athens protocol.

WHAT WAS KNOWN

- Postoperative epithelial remodeling after partial anterior surface normalization with an excimer laser and high-fluence CXL, assessed with high-frequency scanning UBM, results in reduced overall epithelial thickness and topographic variability.

WHAT THIS PAPER ADDS

- Detailed follow-up of Athens protocol-treated eyes up to 1 year confirmed previous ultrasound findings of the overall thinner and smoother epithelial thickness profiles compared with the profiles of untreated keratoconic eyes.

Comparison of prophylactic higher fluence corneal cross-linking to control, in myopic LASIK, one year results

Anastasios John Kanellopoulos^{1,2}
George Asimellis¹
Costas Karabatsas¹

¹Laser-Vision.gr Clinical and Research Eye Institute, Athens, Greece; ²New York University Medical School, New York, NY, USA

Purpose: To compare 1-year results: safety, efficacy, refractive and keratometric stability, of femtosecond myopic laser-assisted in situ keratomileusis (LASIK) with and without concurrent prophylactic high-fluence cross-linking (CXL) (LASIK-CXL).

Methods: We studied a total of 155 consecutive eyes planned for LASIK myopic correction. Group A represented 73 eyes that were treated additionally with concurrent prophylactic high-fluence CXL; group B included 82 eyes subjected to the stand-alone LASIK procedure. The following parameters were evaluated preoperatively and up to 1-year postoperatively: manifest refractive spherical equivalent (MRSE), refractive astigmatism, visual acuity, corneal keratometry, and endothelial cell counts. We plotted keratometry measurements preoperatively and its change in the early, interim and later post-operative time for the two groups, as a means of keratometric stability comparison.

Results: Group A (LASIK-CXL) had an average postoperative MRSE of -0.23 , -0.19 , and -0.19 D for the 3-, 6-, and 12-month period, respectively, compared to -6.58 ± 1.98 D preoperatively. Flat keratometry was 37.69, 37.66, and 37.67 D, compared to 43.94 D preoperatively. Steep keratometry was 38.35, 38.36, and 38.37 D, compared to 45.17 D preoperatively. The predictability of Manifest Refraction Spherical Equivalent (MRSE) correction showed a correlation coefficient of 0.979. Group B (stand-alone LASIK) had an average postoperative MRSE of -0.23 , -0.20 , and -0.27 D for the 3-, 6-, and 12-month period, respectively, compared with -5.14 ± 2.34 D preoperatively. Flat keratometry was 37.65, 37.89, and 38.02 D, compared with 43.15 D preoperatively, and steep keratometry was 38.32, 38.57, and 38.66 D, compared with 44.97 D preoperatively. The predictability of MRSE correction showed a correlation coefficient of 0.970. The keratometric stability plots were stable for the LASIK-CXL group and slightly regressing in the standard LASIK group, a novel stability evaluation metric that may escape routine acuity and refraction measurements.

Conclusion: Application of prophylactic CXL concurrently with myopic LASIK surgery appears to contribute to improved refractive and keratometric stability compared to standard LASIK. The procedure appears safe and provides a new potential for LASIK correction.

Keywords: myopic LASIK regression, femtosecond myopic LASIK, LASIK-CXL, LASIK-Xtra, high myopia, accelerated high-fluence collagen cross-linking

Introduction

Laser-assisted in situ keratomileusis (LASIK) is the most common form of refractive surgery,^{1,2} offering predictable and stable refractive and visual outcomes.³ Specifically, in correcting moderate to high myopia (equal or more than -6.00 D in the least-minus meridian),^{4,5} there have been reports in the past indicating significant long-term regression.⁶⁻⁸ The work by Alió et al⁹ reported that 20.8% of high myopia cases required

cylinder of -0.82 ± 0.03 D. The LASIK-CXL group had, postoperatively, 90.4% of eyes with less than 0.25 D of refractive astigmatism, and mean cylinder of -0.16 ± 0.04 D. The stand-alone LASIK group had 91.5% with less than 0.25 D of refractive astigmatism, and mean cylinder of -0.15 ± 0.04 D.

Refractive and keratometric stability

Refractive stability was demonstrated by the MRSE correction, as followed during the 1-, 3-, 6-, and 12-month postoperative visits (Figure 7). The 1-year mean postoperative MRSE was -0.19 ± 0.17 D in the LASIK-CXL group and -0.27 ± 0.23 D in the stand-alone LASIK group. These findings indicate a reduced refractive shift in the LASIK-CXL group in comparison with the stand-alone group ($P=0.063$). The keratometric stability, demonstrated by the K-flat and

Long-Term Safety and Efficacy of High-Fluence Collagen Crosslinking of the Vehicle Cornea in Boston Keratoprosthesis Type I

Abstract Purpose: To report the long-term safety and efficacy of high-fluence collagen crosslinking (CXL) of the vehicle cornea in Boston Keratoprosthesis (BK) type I. Methods: This retrospective study included 11 patients who underwent high-fluence CXL of the vehicle cornea in BK type I between 2007 and 2012. The mean age was 67 ± 14 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. Results: The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. Conclusions: High-fluence CXL of the vehicle cornea in BK type I is safe and effective. It results in long-term stability of the cornea and allows for continued use of the BK type I. It results in long-term stability of the cornea and allows for continued use of the BK type I.

Introduction The Boston Keratoprosthesis (BK) type I is a unique type of contact lens that is designed to provide long-term visual rehabilitation for patients with severe corneal disease. The BK type I is composed of a central lens and a peripheral skirt. The central lens is made of a special type of plastic that is designed to be compatible with the eye's natural tear film. The peripheral skirt is made of a special type of plastic that is designed to be compatible with the eye's natural tear film. The BK type I is designed to provide long-term visual rehabilitation for patients with severe corneal disease. The BK type I is composed of a central lens and a peripheral skirt. The central lens is made of a special type of plastic that is designed to be compatible with the eye's natural tear film. The peripheral skirt is made of a special type of plastic that is designed to be compatible with the eye's natural tear film.

Methods This study describes the outcomes from 11 patients who underwent high-fluence CXL of the vehicle cornea in BK type I. The mean age was 67 ± 14 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. Results: The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. Conclusions: High-fluence CXL of the vehicle cornea in BK type I is safe and effective. It results in long-term stability of the cornea and allows for continued use of the BK type I.

Results The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. The mean time from CXL to the last follow-up was 3.5 ± 1.2 years. Conclusions: High-fluence CXL of the vehicle cornea in BK type I is safe and effective. It results in long-term stability of the cornea and allows for continued use of the BK type I.

FIGURE 1 Intraoperative images showing the process of high-fluence collagen crosslinking (CXL) of the vehicle cornea in a Boston Keratoprosthesis (BK) type I.

Discussion The purpose of this study was to evaluate the long-term safety and efficacy of high-fluence CXL of the vehicle cornea in BK type I. The results of this study show that high-fluence CXL of the vehicle cornea in BK type I is safe and effective. It results in long-term stability of the cornea and allows for continued use of the BK type I. The results of this study show that high-fluence CXL of the vehicle cornea in BK type I is safe and effective. FIGURE 2 CXL of the cornea, the anterior part of the donor cornea after epithelial debridement, and installation of riboflavin solution with very high-fluence CXL A. The first crosslinking session of the donor cornea through intact epithelium and riboflavin solution injected in the lamellar pocket with 30 mW/cm² for 4 minutes. B, Scraping the donor corneal epithelium with a crescent blade before soaking the stromal surface, in preparation for the second crosslinking session. C, Soaking the deepithelialized donor cornea with riboflavin solution as a preparation for the second crosslinking session.

FIGURE 3 Donor Cornea after 2.8-mm central trephination and just before the peripheral 9.5-mm trephination.

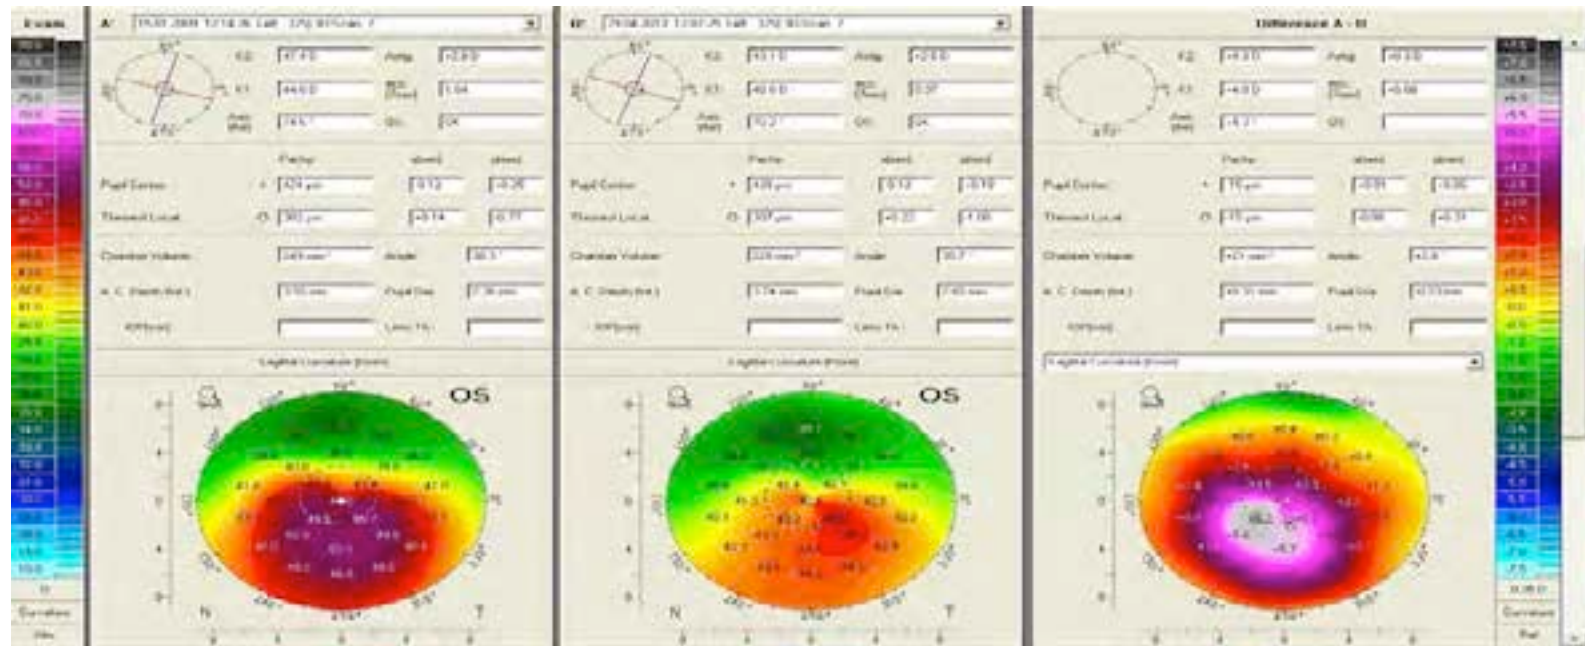

RESULTS

The mean age of the patients was 67 ± 14 years. Six patients were female and 5 were male. The visual acuity assessed from preoperative light perception and/or hand motion showed a 6-month postoperative improvement. The average UDVA was 20/80 (range: 20/100–20/40), and the CDVA was 20/70 (range: 20/80–20/32). These patients are still being followed up. After the first postoperative year, each patient is evaluated at least annually. During the long follow-up time that these patients have been continuously monitored (minimum 1 year, maximum 9 years), 2 of the patients required subsequent injection of intracameral and triamcinolone and bevacizumab injection (Avastin; Genentech/Roche, San Francisco, CA) because of cystoid macular edema. Additionally, 1 patient needed yttrium aluminum garnet laser intervention for a retroprosthesis inflammatory membrane that was quite dense and had resulted in a CDVA reduction from 20/60 to 20/400. After this procedure, the patient's vision returned to 20/50.

Is CXL a refractive procedure?

Most investigators speak of “disease reversal” when flattening occurs after CXL in ectasia

Background: The purpose of this study is to report the safety and efficacy of a new application of collagen cross-linking using a novel device to achieve predictable refractive myopic changes in virgin corneas.

Methods: Four cases were treated with a novel device employing very high-fluence collagen cross-linking applied in a myopic pattern. Prior to treatment, riboflavin solution was applied to the intact epithelium. The collagen cross-linking device was then engaged for a total of 12 J/cm², to be applied transepithelially in a predetermined pattern. Cornea clarity, corneal keratometry, and corneal topography were evaluated by both Placido disc and Scheimpflug imaging, along with cornea anterior segment optical coherence tomography and endothelial cell counts.

Results: An average of 2.3 diopters was achieved in the first week in all four cases treated with the very high-fluence myopic collagen cross-linking intervention. There was a slight regression to 1.44 diopters at 1 month, which remained stable at 6-month follow-up. The mean keratometry change was from 44.90 diopters to 43.46 diopters. There was no significant change in endothelial cell counts or corneal clarity. There was some mild change in epithelial thickness distribution, with the treated area showing a slight but homogeneous reduction in mean thickness from 52 μm to 44 μm.

Conclusion: This report describes the novel application of very high-fluence collagen cross-linking with a predictable well defined myopic refractive (flattening) corneal effect. This technique has the advantages of essentially no postoperative morbidity, immediate visual rehabilitation, and the potential for tapering until the desired result is achieved.

Keywords: myopia, refractive correction, high-fluence collagen cross-linking, clinical results

Introduction

Collagen cross-linking has been used for many years as a means of stabilizing cornea ectasia.¹⁻⁵ Although a multitude of treatments and techniques are available, it has been well documented that the procedure almost invariably results in some central anterior corneal flattening,¹⁻⁵ which has often been interpreted as “disease regression.” As our understanding and the technology available for collagen cross-linking has progressed, it has been theorized that differential application of collagen cross-linking in specific areas of the cornea may produce predictable refractive changes. Several aspects of this theory need further investigation. Is it possible to achieve predictable refractive changes? Can this be achieved through an intact epithelium? Can the human cornea tolerate higher fluence of ultraviolet light? This paper describes the use of a novel

Figure 1 Placido disc topography for patient 3 preoperatively (left) and 6 months postoperatively (right) depicting the significant and regular central corneal flattening effect.

epithelial thickness over the treated area (Figure 3). The average epithelial thickness was 49 μm preoperatively, which decreased to 44 μm at 1 month postoperatively, and then increased to 48 μm at 5 months postoperatively.

Discussion

A multitude of reports have established the significant refractive changes that accompany classic collagen

cross-linking¹⁻⁸ utilizing the classic Dresden protocol (3 mW/cm² for 30 minutes), as well as collagen cross-linking utilizing higher fluence,⁹ and even cross-linking delivered in eyes that have had riboflavin placed within a femtosecond laser-created pocket or intrastromal corneal ring segment channels.^{10,11} Over the years, most clinicians have referred to this process as “flattening,” which has often been interpreted as “disease regression.” We have long

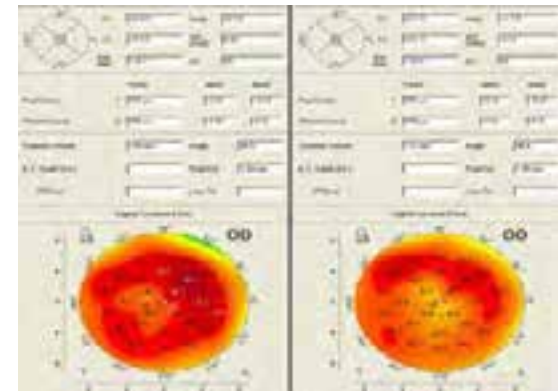

Figure 2 Scheimpflug imaging data for patient 3 preoperatively (left) and 6 months postoperatively (right) depicting the significant and regular central corneal flattening effect. Abbreviations: D, diopters; OD, right eye.

Abstract

Purpose: To report a novel application of toric topographically customized transepithelial collagen cross-linking (CXL) aiming to achieve refractive astigmatic changes in a keratoconic cornea. **Methods:** Specially formulated riboflavin transepithelial administration and delivery of high-fluence UVA in a topographically customized pattern was applied in an eye with progressive keratoconus. Visual acuity, cornea clarity, keratometry, topography, and pachymetry with a multitude of modalities, as well as endothelial cell counts were evaluated for >6 months. **Results:** Uncorrected distance visual acuity changed from preoperative 20/40 to 20/25 at 6 months. A mean astigmatic reduction of 0.8 D, and significant cornea surface normalization was achieved 6 months postoperatively. There was some mild change in the epithelial distribution, with the treated area having a slight normalization in the average epithelial thickness. **Conclusions:** We introduce herein the novel application of a topograph-

Long-Term Safety and Efficacy of High-Fluence Collagen Crosslinking of the Vehicle Cornea in Boston Keratoprosthesis Type I

Annals of Ophthalmology, 2014; 46(9):553-558
 Kanellopoulos and Asimellis

OBJECTIVE: To evaluate the long-term safety and efficacy of high-fluence collagen crosslinking (CXL) of the vehicle cornea in Boston Keratoprosthesis (BK) Type I.

DESIGN: Retrospective, comparative, case series.

SETTING: A tertiary care ophthalmology center.

PATIENTS: Six patients with BK Type I who underwent high-fluence CXL of the vehicle cornea between 2007 and 2011.

MEASUREMENTS AND MAIN RESULTS: The mean age of the patients was 67 ± 14 years. Six patients were female and 5 were male. The visual acuity assessed from preoperative light perception and/or hand motion showed a 6-month postoperative improvement. The average UDVA was 20/80 (range: 20/100–20/40), and the CDVA was 20/70 (range: 20/80–20/32).

CONCLUSIONS: High-fluence CXL of the vehicle cornea in BK Type I is a safe and effective procedure that improves visual acuity and reduces the need for subsequent interventions.

Cornea • Volume 33, Number 9, September 2014

Surgical Technique

The study describes the technique of a 4-minute, high-fluence CXL of the vehicle cornea in BK Type I. The procedure was performed in a tertiary care ophthalmology center. The study included 6 patients who underwent high-fluence CXL of the vehicle cornea between 2007 and 2011. The mean age of the patients was 67 ± 14 years. Six patients were female and 5 were male. The visual acuity assessed from preoperative light perception and/or hand motion showed a 6-month postoperative improvement. The average UDVA was 20/80 (range: 20/100–20/40), and the CDVA was 20/70 (range: 20/80–20/32).

RESULTS

The mean age of the patients was 67 ± 14 years. Six patients were female and 5 were male. The visual acuity assessed from preoperative light perception and/or hand motion showed a 6-month postoperative improvement. The average UDVA was 20/80 (range: 20/100–20/40), and the CDVA was 20/70 (range: 20/80–20/32).

High-Fluence CXL in Keratoprosthesis

The study describes the technique of a 4-minute, high-fluence CXL of the vehicle cornea in BK Type I. The procedure was performed in a tertiary care ophthalmology center. The study included 6 patients who underwent high-fluence CXL of the vehicle cornea between 2007 and 2011. The mean age of the patients was 67 ± 14 years. Six patients were female and 5 were male. The visual acuity assessed from preoperative light perception and/or hand motion showed a 6-month postoperative improvement. The average UDVA was 20/80 (range: 20/100–20/40), and the CDVA was 20/70 (range: 20/80–20/32).

FIGURE 1. Intraoperative view of CXL through the Boston Keratoprosthesis (BK) Type I. The riboflavin solution is administered to the vehicle cornea through the BK Type I.

CXL of “vehicle” cornea in Boston Keratoprosthesis type I: J. Cornea 2014

A. John Kanellopoulos, MD

Conclusions / Our current CXL protocols

1-Athens Protocol: topo partial PRK +15'x 6mw/cm²

or combined with PiXL (4-20 Joules)

2-LASIK Xtra: 1' soaking and 60" 30mW/cm² (1.8 Joules) for all hyperopes, 80" for myopes (2.4 Joules)

2-PRK Xtra: 1' soaking 80" X 30mW/cm² (2.4 Joules)

5-Transepi CXL: 0.25% ribo + 30mW X 3'

6-Infection: 0.25% riboflavin + 20mW/cm² /20 Joules

7-PiXL 0.25% ribo + 30mW/cm² 7.2-20 Joules

Prospective randomized trials have yet to establish the comparative efficacy of the multitude of CXL technique available today

Topography - Guided University Courses 2016:

Become proficient interpreting in cornea diagnostics and designing expert topography guided laser treatments!

Topography - Guided University Courses 2016:

Become proficient interpreting in cornea diagnostics and designing expert topography guided laser treatments!

Didactic course and hands-on treatment designing of multiple case scenarios (virgin eyes, complicated therapeutic treatments; older decentered or irregular ablations, cornea scars, ectasia and keratoconus). How to adjust optical zone, transition zone, and account for topography spherical neutralization. Each participant will bring his or her clinical cases and design a treatment, and/or will be given all of the case scenarios noted above to design a treatment. Anticipate spherical change surprises. Modulation of biomechanics with various CXI protocols.

- Outline and 2016 locations
- Pre-ESGRS
- Pre-AAO

Copenhagen '16 course logistics

Friday September 9th, 2016
(pre-ESGRS)

8:00 AM to 15:30 PM

At the Crowne Plaza
 Copenhagen Towers
 Ørestads Boulevard 114 - 118
 2300 København S, Denmark
 info@cpcopenhagentowers.com
 Tel: +45 8877 6655
 Fax: +45 8877 6611

Chicago '16 course logistics

Thursday October 13th, 2016
(pre-AAO)

8:00 AM to 15:30 PM

At the Hyatt Regency McCormick Place
 2233 S Martin Luther King Dr,
 Chicago, 60616, IL, USA
 Tel: +1 312 567 1234

2016 Course's Mutual Outline (Copenhagen and Chicago)

8:00
 Breakfast - Registration

8:30-11:30

- Introduction to current cornea diagnostics and their relative differences: Placido Topography, Scheimpflug tomography, Anterior segment OCT, LED color reflection topography.
- Corneal epithelial mapping and its clinical relevance in diagnosis and treatment
- Basic principles in employing topography data (Scheimpflug based and/or Placido-based) in the customization of an excimer corneal ablation. Technology overview and case presentations, with the Wavelight, Schwind and Ivis platforms.
- Topography astigmatism, centroid and angle kappa considerations for possible revision of the clinical refraction used in each ablation

11:30-12:30

Discussion lunch

12:30-15:30

- Topography customized methodology for virgin myopic and hyperopic eyes
- Topography customized methodology for irregular corneas (previously treated: RK, decentered and/or irregular ablations, as well as irregular and ectasia cases)
- Anticipating asphericity and sphere compensatory nomograms for better spherical correction and emmetropia.
- Participants will gain access to an online database with over 100 cases examples (pre-op data, treatment design, treatment video, postop data and overview of what went well and what potentially went off-target)
- Complications assessment and management.

- Each participant will have the chance to design several treatments on site!

The course will be limited to 30 participants.

Advanced registration and information:

Topography - Guided University Courses 2016:

- Correlation of multiple corneal imaging devices may enhance accuracy of assessment by including possible epithelial remodeling data, and limiting specific limitations of Placido-based, Scheimpflug-based and color LED refraction Topography.
- When using topography maps in laser corneal ablation, all these parameters are considered under a much more meticulous and critical perspective. Although originally designed to treat irregular eyes, it has recently become apparent, that topo-guided treatments may be superior for routine myopic and/or hyperopic laser vision correction.
- This vigorous didactic course and wet lab on topography-customized corneal ablations will focus on familiarizing the small number of participants on multiple imaging assessment and interpretation, data acquisition and treatment modifications with hands-on the design platforms and data present on-site.
- Additionally, the participants will be offered access to a very large databank with most topo-guided scenario treatments and outcomes.
